Conventional Lot Acceptance Sampling Plan Design

OC Curve: n, c = 0
$$p(accept) = (1-p)^n$$
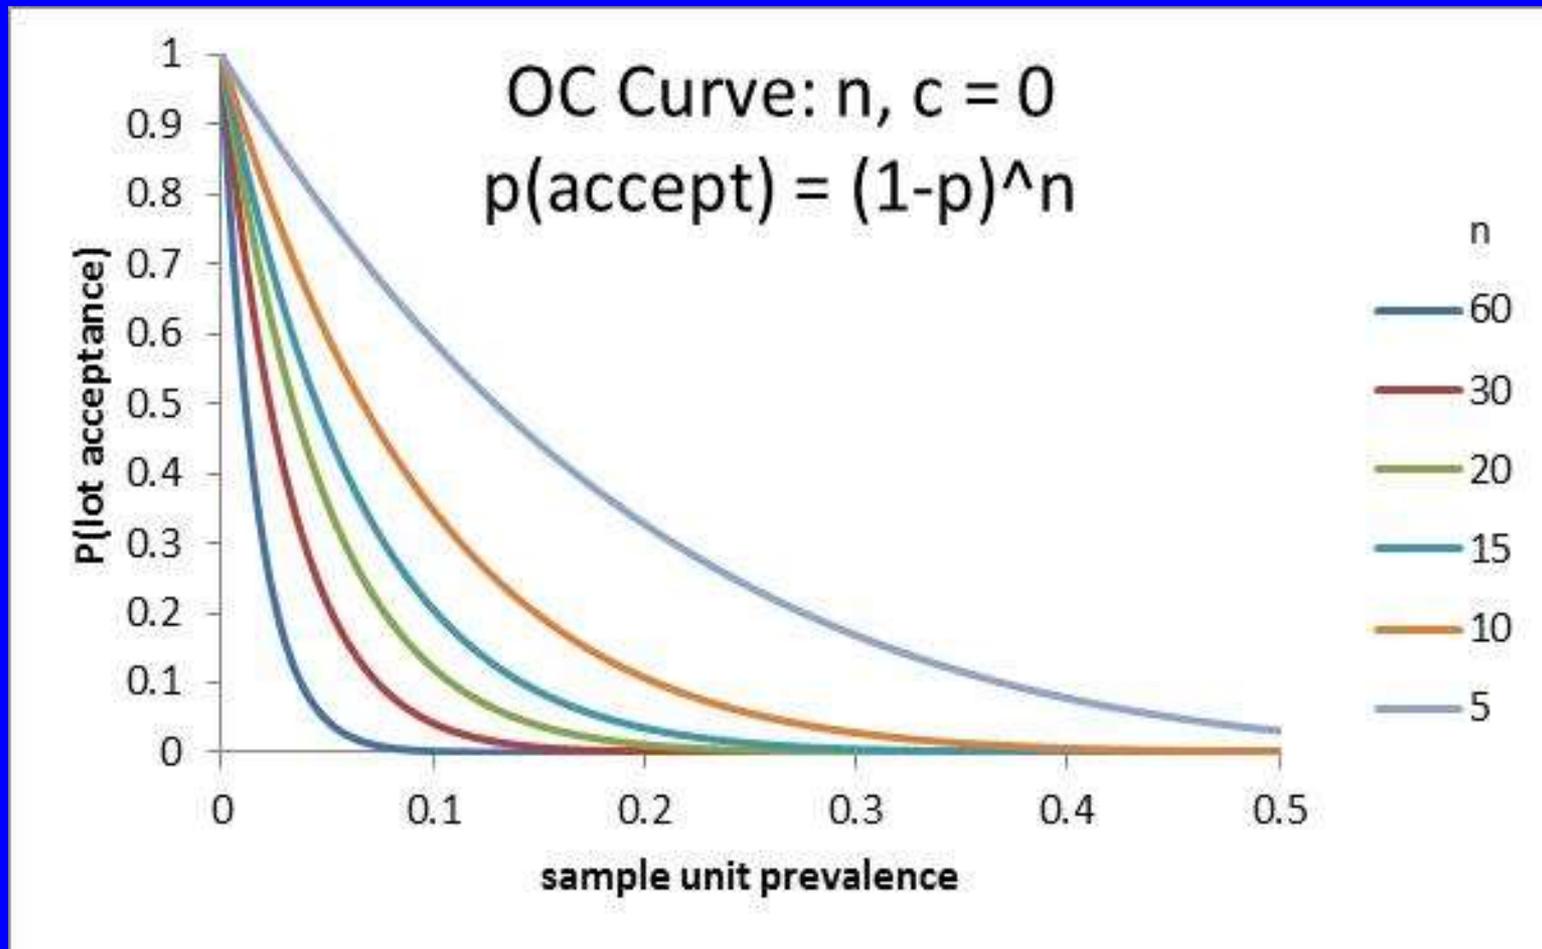

Simple Optimization Model

- $Max \; L_R = m[1 - q^n]$
  - L_R = contaminated lots rejected
  - m = lots
  - n = samples per lot
  - $q = (1 - p)$
  - p = sample unit prevalence
  - $1 - q^n$ = p(reject lot)
- *S.t.:* Budget constraint (C_T)

Simple Optimization Model

- $Max \; L_R = \dfrac{C_T}{C_l + nCn}[1 - q^n]$

  - $m = \dfrac{C_T}{C_l + nC_n}$ (budget constraint)
  - $C_T =$ budgeted total sampling cost (\$)
  - $C_l =$ cost per lot (\$)
  - $C_n =$ cost per sample (\$)

$$n_{opt}(C_T, C_l, C_n, p) \rightarrow \frac{\delta(L_R)}{\delta(n)} = \frac{[C_l + nC_n][-C_T q^n ln(q)] - [C_T(1 - q^n)]C_n}{[C_l + nC_n]^2} = 0$$

Simple Optimization Model

- Obj Fxn: $L_R = m(1 - q^n) = f(m, n|q)$
- Constraint: $C_T \geq m(C_l + nC_n)$
- $L = f(m, n|q) + \lambda[C_T - m(C_l + nC_n)]$

Simple Optimization Model

1) $\frac{\delta L}{\delta m} = \frac{\delta f}{\delta m} - \lambda(C_l + nC_n) = 0$

2) $\frac{\delta L}{\delta n} = \frac{\delta f}{\delta n} - \lambda mC_n = 0$

3) $\frac{\frac{\delta f}{\delta m}}{\frac{\delta f}{\delta n}} = \frac{C_l + nC_n}{mC_n}$

4) $n = \frac{\frac{\delta f}{\delta m}}{\frac{\delta f}{\delta n}} m - \frac{C_l}{C_n}$

5) $\frac{\frac{\delta f}{\delta m}}{\frac{\delta f}{\delta n}} = \frac{(1-q^n)}{-mq^n ln(q)}$
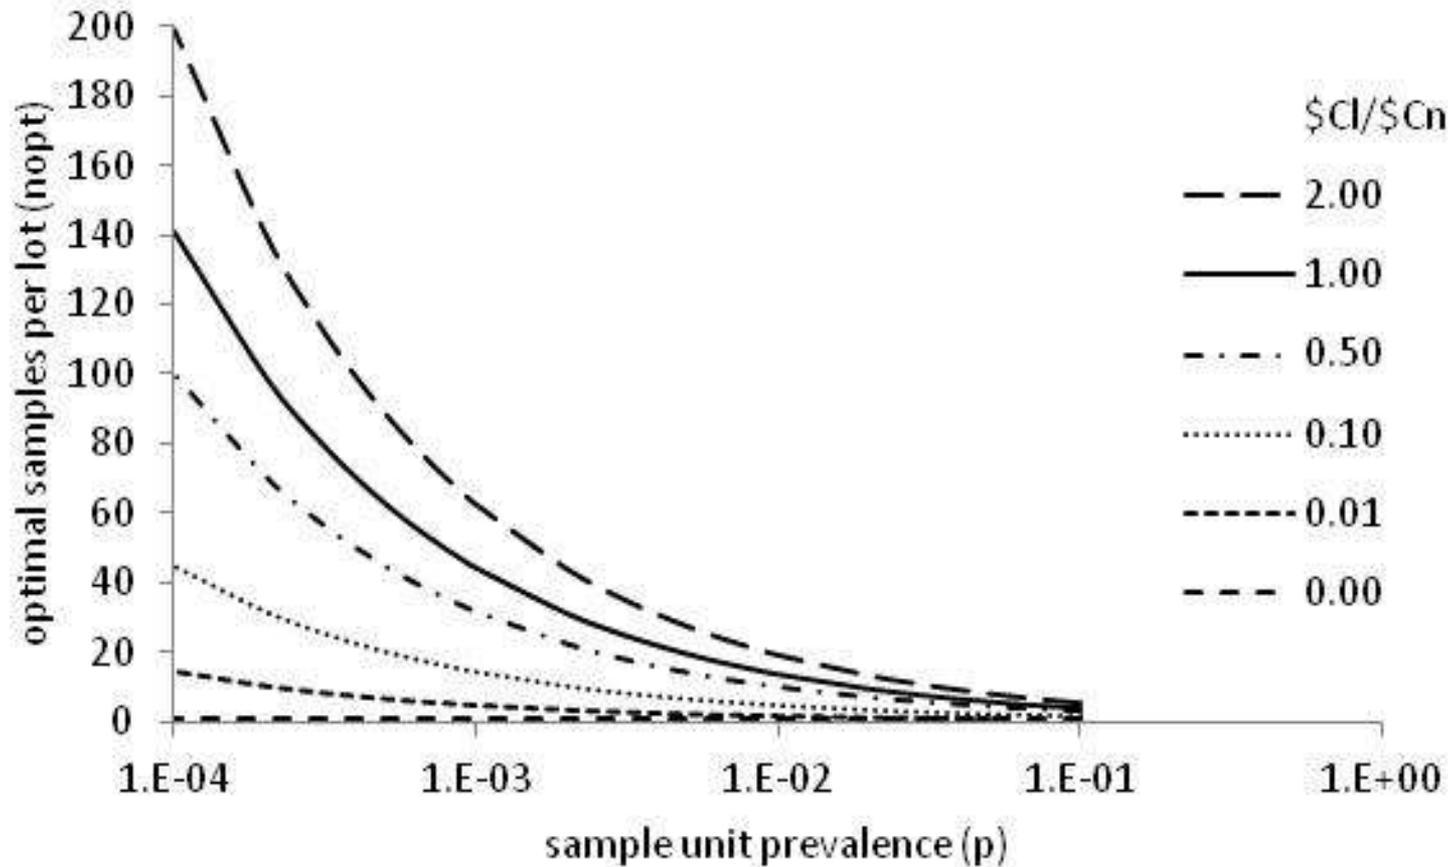

6) $n + \frac{(1-q^n)}{q^n ln(q)} + \frac{C_l}{C_n} = 0$
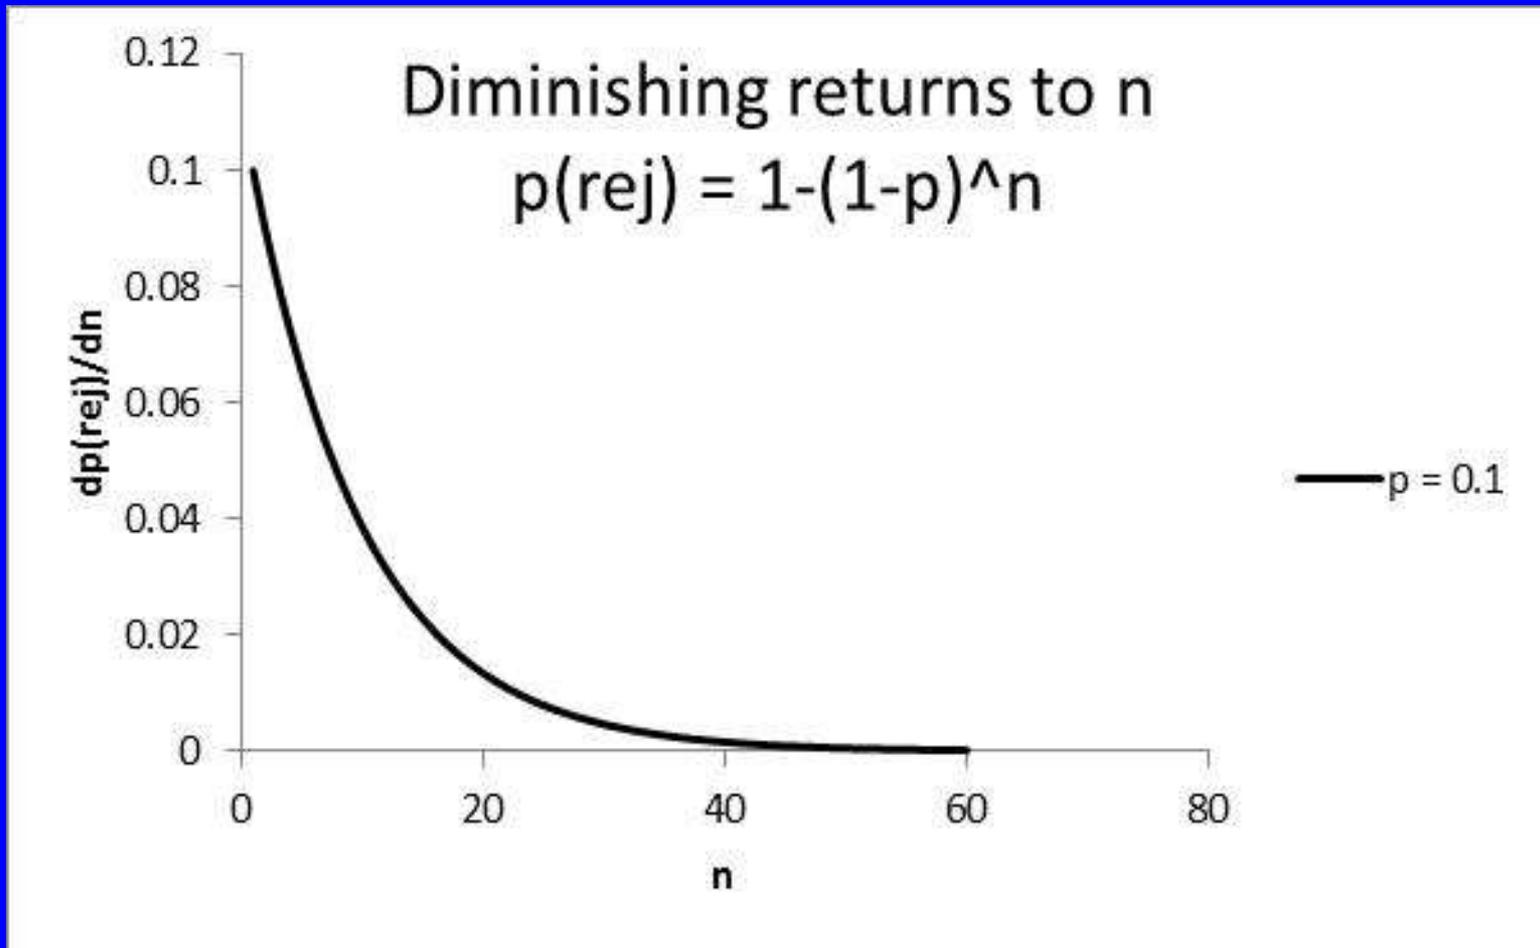

Note: $n_{opt} = f\left(p, \frac{C_l}{C_n}\right)$

Results

- If budget constraint does not permit testing 100% of lots, n_{opt} for a given sample unit prevalence (p) depends only on the cost ratio (C_l/Cn).

- The budget constraint (C_T) determines absolute number of lots tested in a budget period (m) or the frequency of lot inspection $(1/m)$

Results

Results

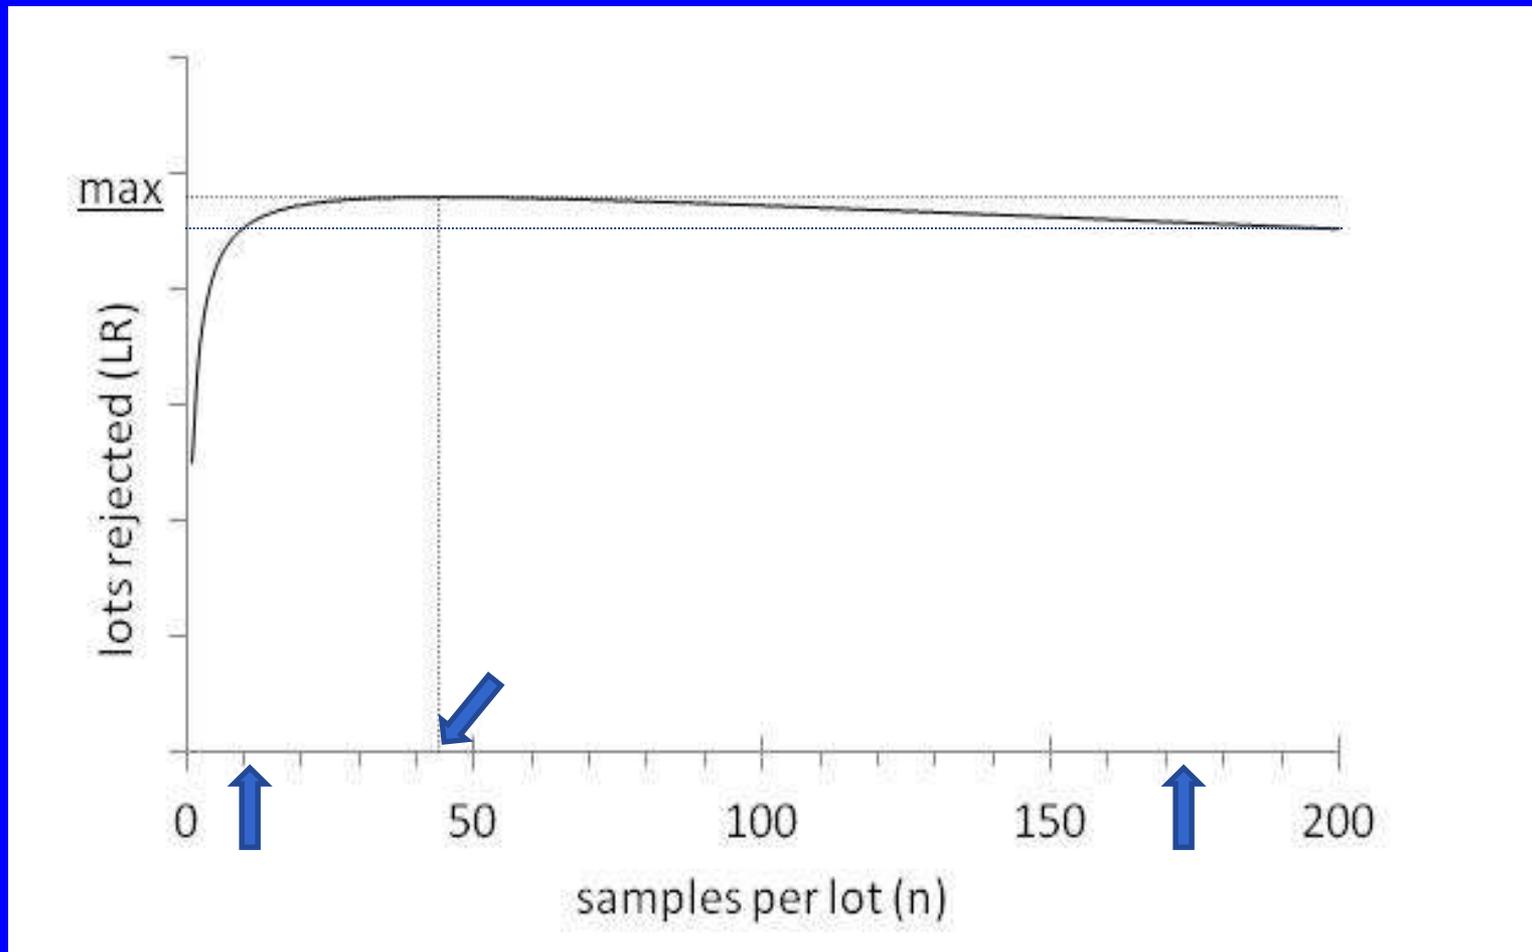

Diminishing returns to n
$p(rej) = 1-(1-p)^n$

p = 0.1

Results

$$\$C_l/\$C_n = 1 \text{ and } p = 10^{-3}$$

Conclusion

- National Research Council (1985): sampling plans based on "sound statistical concepts" need to "achieve a high degree of confidence in the acceptability of a lot."

- Economic design of measures is not new.

- Scarce resources should force us to consider the tradeoff between depth (n) and coverage (m).

- Multiple, competing objectives for sampling.

Modern Portfolio Theory

- Markowitz (1952) Mean Variance Optimization (MVO):

$$Min_w \ \boldsymbol{w}^T \textstyle\sum \boldsymbol{w} = \sigma_p^2$$

$$\boldsymbol{w}^T \boldsymbol{\mu} = \mu_p^*$$

$$\boldsymbol{w}^T \mathbf{1}_N = 1$$

$$\boldsymbol{w} = \begin{bmatrix} w_1 \\ \vdots \\ w_N \end{bmatrix}$$

$$\mu = \begin{bmatrix} \mu_1 \\ \vdots \\ \mu_N \end{bmatrix}$$

$$\Sigma = \begin{bmatrix} \theta_1^2 & \cdots & \theta_{1N} \\ \vdots & \ddots & \vdots \\ \theta_{N1} & \cdots & \theta_N^2 \end{bmatrix}$$

Sharpe Ratio (S) $= \dfrac{\mu_p}{\sigma_p}$

Limitations of Mean-Variance Optimization

- Extreme asset weights
- Weights sensitive to small changes in inputs
- Poor out-of-sample performance
- Assumes stationary process
- # parameters $(\mu_i, \sigma_i^2, \sigma_{ij}) = 2N + (N*(N-1)/2)$
- Model uncertainty

Limitations of Mean-Variance Optimization

- Sensitivity of the model to input errors
  - Frankfurter et al. 1971. "Portfolio Selection: The Effects of Uncertain Mean, Variances, and Covariances" The Journal of Financial and Quantitative Analysis 6(5): 1251-1262.
  - Hodges and Brealey. 1972. "Portfolio Selection in a Dynamic and Uncertain World" Financial Analysts Journal 28(6): 58-69.

Limitations of Mean-Variance Optimization

Example of sensitivity to estimation error

- Obj: max $S = \mu_p / \sigma_p$
- Consider two identical assets, A and B:
  - $\mu_A = \mu_B = 10\%$; $\sigma_A = \sigma_B = 5\%$; $\rho_{AB} = 0.9$
  - true optimal weights: $w_A = w_B = 0.5$
- Assume μ_A estimated with 10% error:
  - $\bar{x}_A = 11\%$
  - est. optimal weights: $\hat{w}_A = 0.95$; $\hat{w}_B = 0.05$

Limitations of Mean-Variance Optimization

- Naïve portfolio formation rules, such as the equal weight (1/N) rule, can outperform MVO.

  – Bloomfield, T., R. Leftwich, and J. Long. 1977. Portfolio Strategies and Performance. Journal of Financial Economics 5:201–18.

Limitations of Mean-Variance Optimization

- Very long history of returns needed to estimate mean excess return accurately

- Even if long time series are available, may not be reasonable to assume the parameters were stationary over that long a period

  – Merton. 1980. On Estimating the Expected Return on the Market. NBER Paper 444.

Limitations of Mean-Variance Optimization

- Given estimation uncertainty, optimal portfolio not well-defined; statistically equivalent portfolios with very different asset weights

  – Michaud. 1989. "The Markowitz Optimization Enigma: Is 'Optimized' Optimal?" Financial Analysts Journal. 45: 31-42.

DeMiguel et al (2007) Optimal versus Naïve Diversification

- Evaluated out of sample performance of sample-based MVO and its extensions designed to reduce effects of estimation error.

- 14 optimizing portfolio models compared to naïve diversification (1/N)

- 7 datasets of monthly returns

- Optimization models -10 year moving estimation window to predict next month's performance.

- 3 criteria: Sharpe ratio, CEQ return, and turnover

DeMiguel et al (2007) Optimal versus Naïve Diversification

- None of the portfolio optimization models performed consistently better than 1/N portfolio

- Estimation window needed for MVO and its extensions to outperform 1/N:

  ~ 3000 months for N = 25 portfolio

  ~ 6000 months for N = 50 portfolio

Optimal vs. Simple: Simulation

- Let $i = 1, ..., 27$ producers; $j = 1, ..., 20$ yrs.

Factor	hi	med	low
Mean lot prevalence (μ)	0.01	0.005	0.001
CV lot prevalence (σ/μ)	2	1	0.5
Volume (L_t, lots/yr)	100,000	10,000	1,000

- Lot prevalence (p_i) ~ Beta(μ_i, σ_i)

- Freq. of lot inspxn ~ 1% (budget constraint)

- $\Sigma_i I_{ij}$ (lot inspxns)/yr. ~ 9,990

- $p_{detxn} = 78.5\%$ (e.g., $p_{w/in} = 5\%$, n/lot = 30)

Optimal vs. Simple: Simulation

- Simulation of Contaminated Lots & Inspection
  - #contam lots (c_{ij}) ~ Binomial(L_i, p_i)
  - #contam lot inspected (ci_{ij}) ~ Hypergeo(I_{ij}, c_{ij}, L_i)
  - #contam lots detected (x_{ij}) ~ Binomial(ci_{ij}, p_{detxn})
- Optimal Allocation: $I_{ij} \propto L_i * \hat{p}_{ij}$
  - s.t. $I_{i1} = 9990/27 = 370$; $1 \leq I_{ij} \leq L_i$ for j = 2, …, 20

  - $\hat{p}_{ij} = \frac{\sum_{t=1}^{j-1} x_i}{\sum_{t=1}^{j-1} I_i}$

- Simplified Allocation: $I_i \propto L_i$

Optimal vs. Simple: Simulation

Optimized Allocation

Producer 3 (Hi Vol, Hi Prev, Low CV)
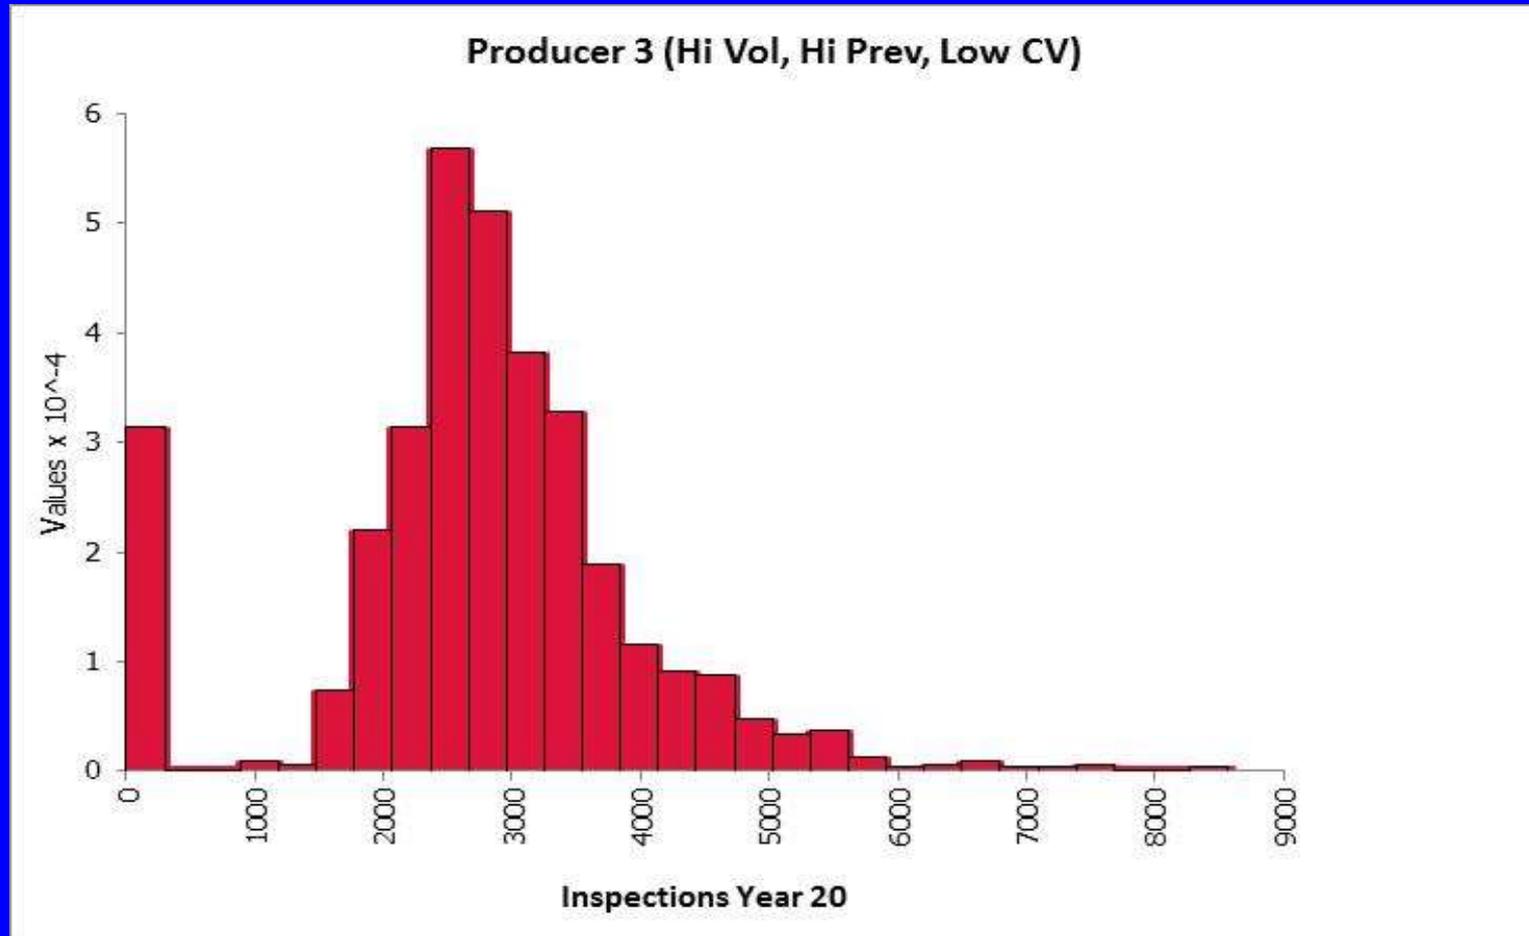

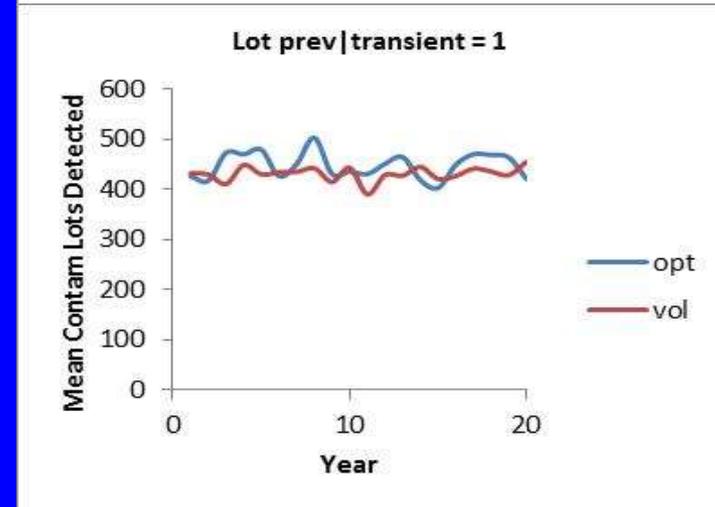

Optimal vs. Simple: Simulation
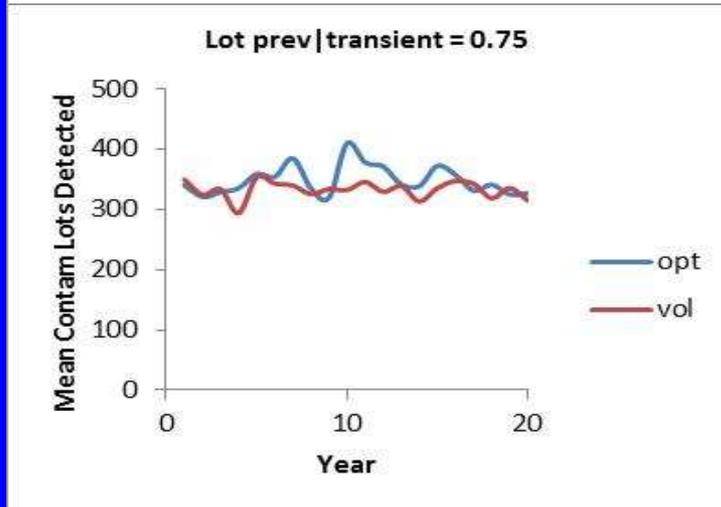

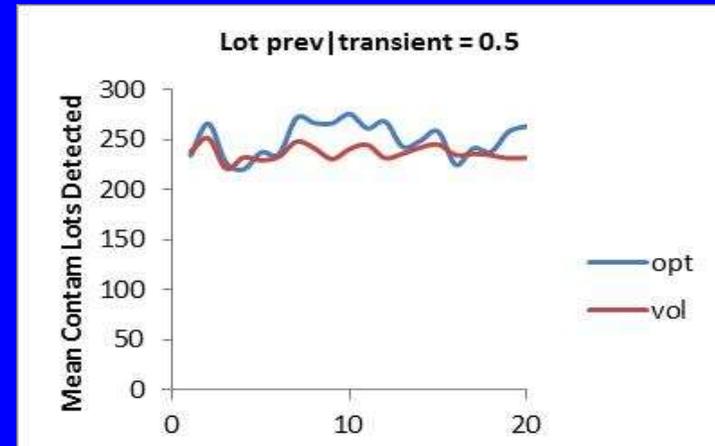

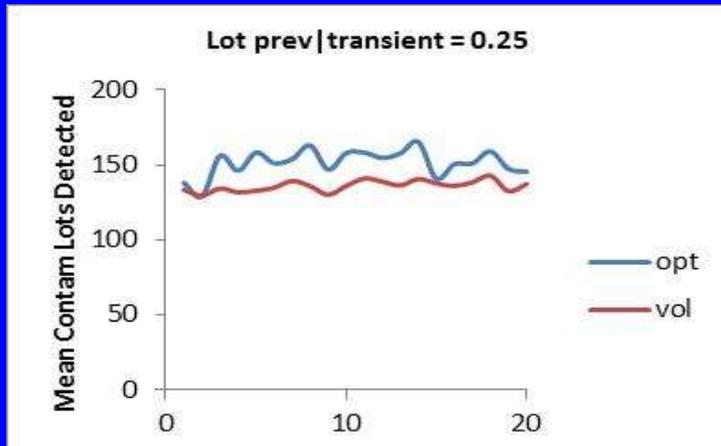

Optimized Allocation
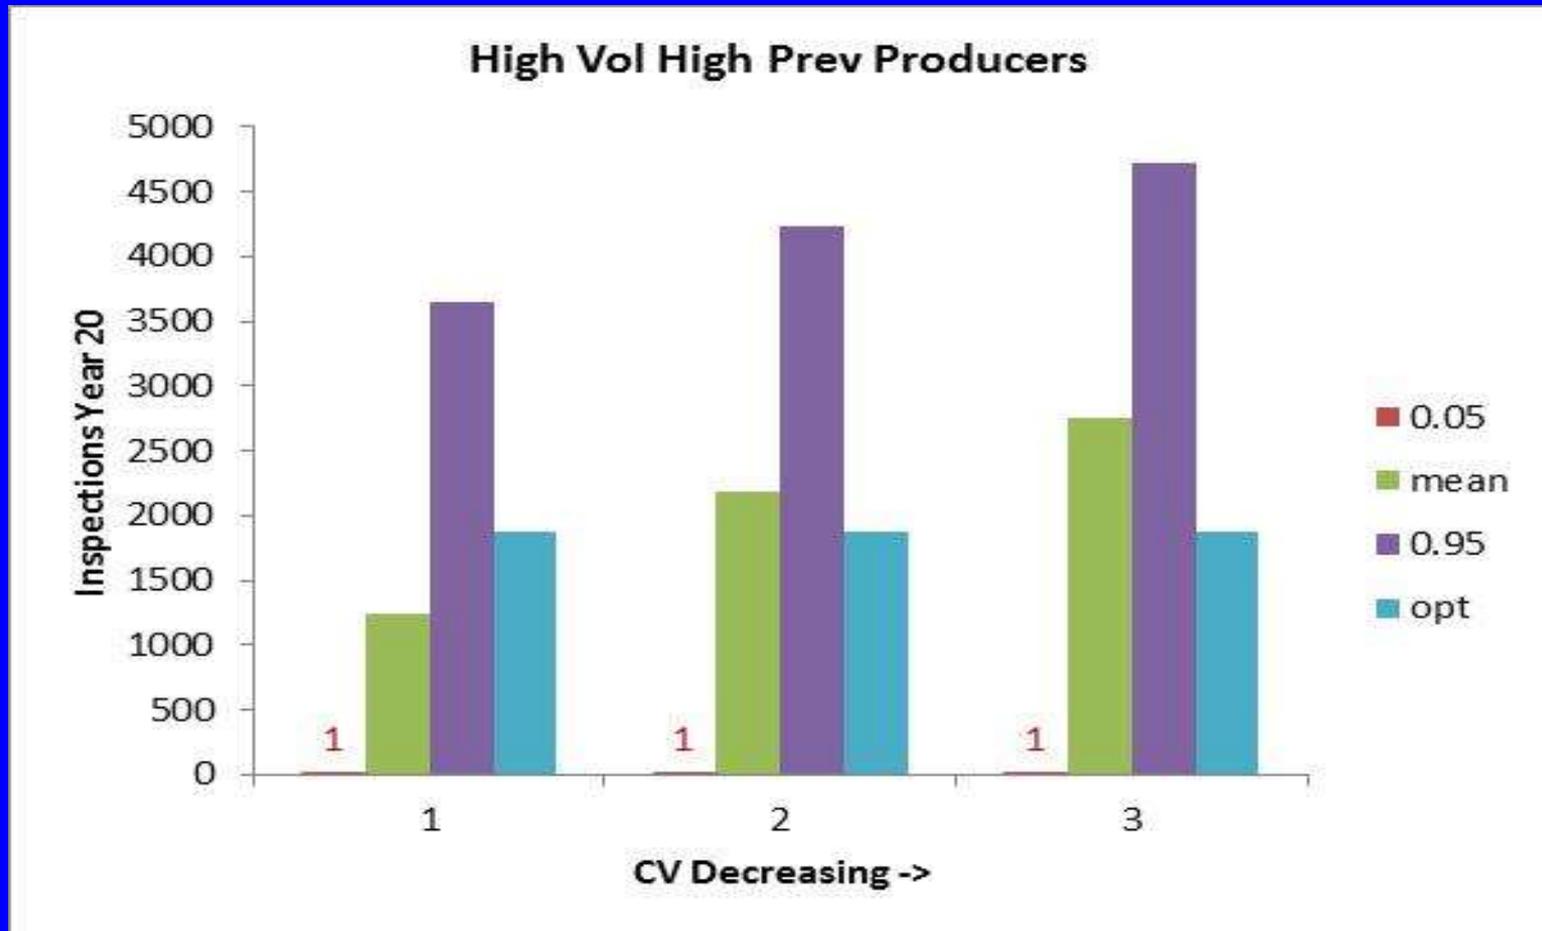

Optimal vs. Simple: Simulation

Process Stationary over 20 years
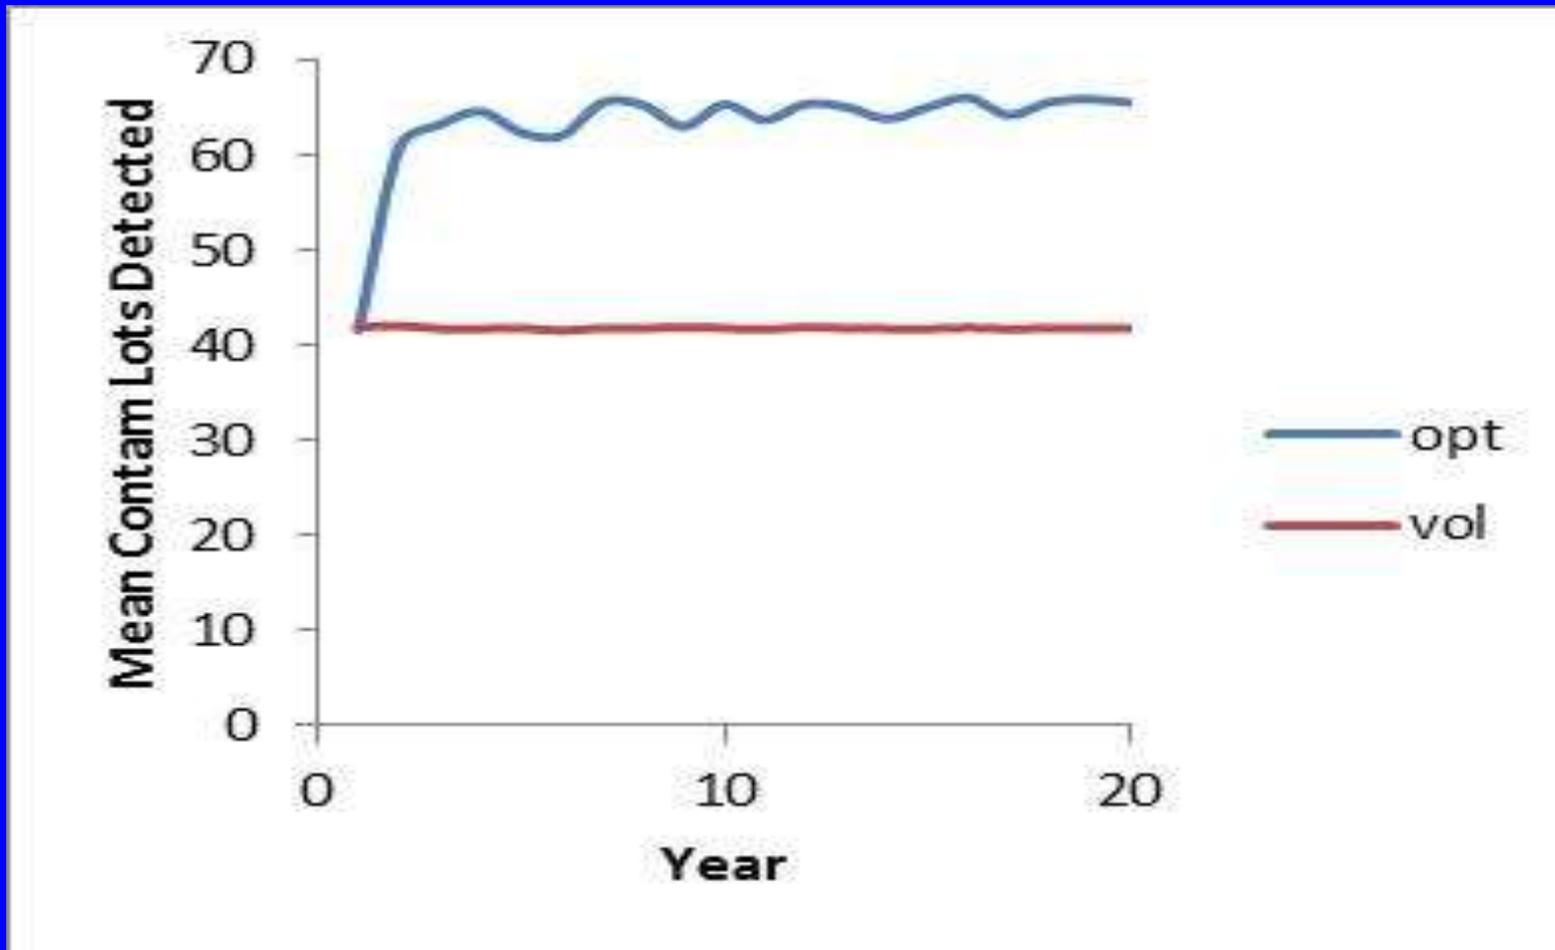

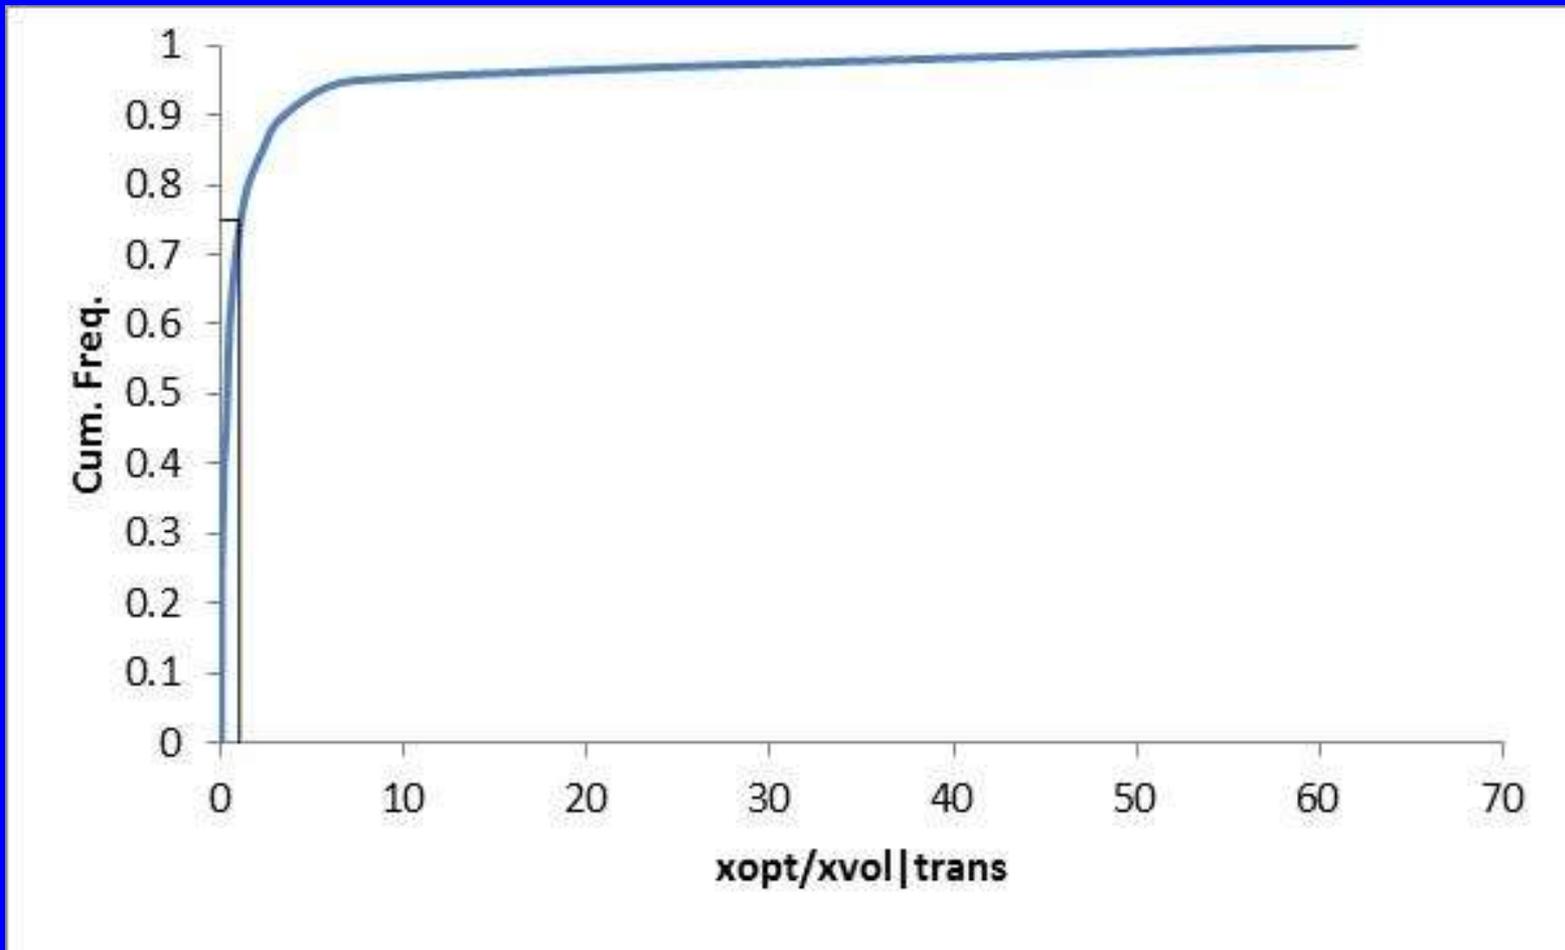

Optimal vs. Simple: Simulation

Producer's annual p(transient) = 0.05/yr. (1/20 years)

Optimal vs. Simple: Simulation

Producer's annual p(transient) = 0.05/yr. (1/20 years)

Optimal vs. Simple
